Abstract

The widening gap between the cost of meeting family planning needs and the funding available for commodities and programmes is a concern among policymakers and reproductive health professionals. The gap could reach US\$210 million by 2015. Its causes are clear; its solutions are not. While changes in programme method mix and cost shifting could address this gap, an often-overlooked alternative is the development and introduction of effective, low-cost methods. The Standard Days Method™ (SDM) has a first-year failure rate of only 4.8 (correct use) and is acceptable to many women around the world. It is easily integrated into programmes. Many SDM users rely on CycleBeads™ to help identify the days when pregnancy is likely. Though already meeting couples' needs in many places, the SDM responds in a unique way to needs in settings with high use of traditional methods, high levels of unmet need, and chronic depletion of commodities. The donor gap could have negative consequences, but it also facilitates reassessing family planning programme policies to include other effective, low-cost methods.

The donor gap

Fuelling the donor gap is the growing demand for family planning around the world. One factor affecting demand is the increasing number of people of reproductive age. In 2000, there were an estimated 1.261 billion women between the ages of 15 and 49 years in developing countries; that number is expected to reach 1.548 billion by 2015.¹ These additional 287 million women – almost 23% more than in 2000 – will place a heavy burden on family planning programmes, even if contraceptive prevalence does not increase. A second factor affecting the demand for commodities is growing contraceptive prevalence. In 2000, prevalence among women in acknowledged relationships (union living) in developing countries was estimated at 59.8%; by 2015 it is estimated to be 65.4%.¹ As a result of the increase in prevalence, coupled with the growth in the number of women of reproductive age, current funding levels will no longer be sufficient to meet family planning needs.

What about the costs of the commodities to meet the growing demand for family planning? Table 1 presents three pricing estimates for contraceptive commodities: Bulatao's 1999 estimates based on United Nations Population Fund (UNFPA) schedules, US Agency for International Development (USAID) prices in 2000 and Saunders' 2001 estimates for UNFPA.^{2–4} The per-unit costs are the basis for estimating the commodity cost ranges for 1 year of method use. For example, if a pack of pills costs between \$0.175 and \$0.287 then 15 packs, which is the number used by USAID to calculate one couple-year of protection, would cost between \$2.28 and \$3.73. Costs of coitus-dependent methods (condoms and spermicides) are based on Stover and colleagues' finding that people who use those methods have intercourse, on average, 64 times per year, an estimate that is much lower than the 105–120 units used to measure one couple-year of protection.⁵ If a couple uses vaginal spermicides, an estimate of the annual cost of the commodities would range from \$3.84 to \$8.00.

When joining the demand for contraception with the cost of the commodities, the significance of 'the gap' becomes apparent. After the International Conference on Population and Development in 1994, donations increased briefly, reaching \$172 million in 1996, but dropped to \$131 million in 1999.³ By 2015, Ross and Bulatao project the cost of commodities to reach approximately \$350 million, a 155% increase over the 1997–1999 average donation level of \$147 million.³ They then estimate the size of the gap based on two financing scenarios. In one scenario donor funding increases at 3% per year from the 2000 level and the gap reaches \$140 million by 2015. In the second scenario donor funding for commodities is held constant at the 2000 level (approximately \$140 million) and the gap reaches \$210 million in 2015. While these scenarios represent hypothetical situations, they illustrate a point on

Key message points

- The 'donor gap' is being created by the growing demand for family planning services and funding levels that do not keep pace with the growing need.
- One alternative to alleviating the donor gap is the introduction of low-cost, simple, effective methods of family planning, such as the Standard Days Method (SDM).
- Though meeting the family planning needs of many couples, introducing the SDM is especially important in settings with high reliance on traditional methods, high levels of unmet need for family planning, and chronic depletion of contraceptive commodities.

Introduction

The burgeoning gap between the cost of meeting the growing demand for family planning and the limited funding for contraceptive commodities in developing countries is known as the 'donor gap'; the donors being government development agencies, United Nations organisations, the World Bank and international family planning organisations. Just as riders of the London Underground are warned to 'mind the gap' to avoid falling and hurting themselves, policymakers and the reproductive health community have received a similar warning that insufficient funding for family planning commodities is creating a dangerous situation that could hurt countless women and men around the world. The causes of the donor gap are clear; its solutions are not. This commentary explores possible consequences of the gap, and highlights an often-overlooked alternative.

Table 1 Costs of contraceptive commodities, estimates from 1999 to 2001

Method	Cost/unit (US\$)			Units needed/year	Cost/year (US\$)
	UNFPA (1999) ²	USAID (2000) ³	Saunders (2001) ⁴		
Short-term methods					
Pill	0.287	0.217	0.175	15 packs	2.28–3.73
Injectable	1.100	0.970	0.675	4 shots	2.70–4.40
Condom	0.026	0.066	0.025	64 units	1.60–4.22
Vaginal spermicides	0.099	0.125	0.060	64 units	3.84–8.00
Long-term methods					
Norplant®	NA	23.80	23.00		6.57–6.80
Female sterilisation	10.64	NA	NA		1.20
Male sterilisation	5.92	NA	NA		0.67
IUD	1.65	1.45	NA		0.41–0.47

Cost data sources: Bulatao (1999)², Ross and Bulatao (2001)³ and Saunders (2001)⁴. Condom and vaginal spermicide costs/year based on 64 acts of intercourse per year. Long-term methods cost/year based on couple-years of protection (CYP) (i.e. sufficient commodity to provide contraception for one couple for 1 year) factor published by Stover et al. (2000)⁵. NORPLANT based on 3.5 CYP, sterilisation based on 8.9 CYP and IUD based on 3.5 CYP. IUD, intrauterine device; NA, not available; USAID, US Agency for International Development.

which everyone is in agreement: donor funding for contraceptive supplies is not keeping pace with the increasing demand for family planning.

Solutions to the donor gap

If the donor gap continues to grow and huge shortfalls in funding for commodities become a reality, what can programmes do to minimise the adverse effects of the situation? Options could include changing donor levels and restrictions; sharing and shifting costs; and introducing alternative, less costly methods.

The most straightforward option involves donors. Raising donor levels and easing restrictions could enable their contributions to have a greater impact on responding to growing needs. However, neither change seems likely under current economic and political conditions. Given that the gap represents as much as 150% of current donor levels, it is not likely that future donations alone will be able to close the gap.

Cost-sharing, which is frequently discussed in the context of contraceptive security initiatives, is another possibility for maintaining current levels of programme effort.⁶ In that scenario the government and public are called upon to shoulder a greater share of the costs of commodities. One option is for those governments to pass on the additional costs through user fees in the public sector. In some countries this option could be feasible and represents the goal of many health sector reforms. Market segmentation would help identify those individuals most in need of subsidised contraceptives, and require others to pay for family planning. Studies have found that a sizeable percentage of women relying on subsidised pills from the public sector could, in fact, afford to pay for them.^{7,8} Programmes to stimulate the commercial sector could make it a more viable source for family planning. An alternative cost-sharing approach is for communities to use mechanisms such as user fees, revolving funds and insurance programmes as a way to finance family planning commodities and services.

Rather than cost-share, governments could cost-shift by removing some of the more expensive methods from the public sector programme mix. For example, the cost per year of implants and spermicides is much higher than other methods, and in a critical situation the decision might be made to curtail the availability of these methods, at least in the subsidised sector. Along the same line, governments could shift to an emphasis on long-term methods, which would ultimately improve programme cost-effectiveness. Such decisions would drastically reduce the number of choices available to women and men, particularly those methods that contribute to child spacing. In spite of the negative implications for informed choice and quality of

care, these options need to be considered as possible courses of action in response to the donor gap.

A more positive alternative is the development and introduction of new, low-cost methods. In a recent workshop on family planning programmes in the 21st century, cost was cited as the leading factor limiting the availability of long-term hormonal contraceptives, which represent many of the technologies currently being developed.⁹ Given the projected donor gap, high-cost methods will place an excessive financial burden on already depleted programmes. Perhaps low-cost methods need to be given greater attention.

A cost-effective alternative: the Standard Days Method

A new method that is being introduced into programmes is a fertility awareness-based method, the Standard Days Method™ (SDM). It identifies a fixed fertile window in the menstrual cycle and helps users to be aware of the days when pregnancy can occur. To prevent pregnancy, the couple avoids unprotected intercourse on Days 8 to 19 of the woman's cycle. Many couples choose to use condoms when they have intercourse during the fertile days.^{10–12} In a multi-site efficacy study, the SDM was found to have a first-year failure rate of 4.8 when used correctly, and 12.0 with typical use, comparing favourably to other user-dependent methods, as shown in Table 2.^{13,14} The method is easily integrated into primary health care programmes, family planning associations, as well as non-health, non-governmental organisations.¹⁵ Experienced family planning providers can be trained to offer the SDM in as little as a half day.

Table 2 Rates of unintended pregnancies during the first year of typical and correct use of user-dependent family planning methods

Method	Pregnancy rate	
	Typical use	Correct use
Chance	85	85
Spermicides	26	6
Cervical cap		
Parous women	40	26
Nulliparous women	20	9
Sponge		
Parous women	40	20
Nulliparous women	20	9
Diaphragm	20	6
Condom		
Male	14	3
Female	21	5
Standard Days Method™	12	5

Sources: Hatcher et al. (1998)¹⁴ and Arévalo et al. (2002)¹³. NB. Pregnancy rates are drawn from studies using different methodologies and may not be directly comparable.

Figure 1 CycleBeads™: a tool to help users of the Standard Days Method™ identify days when pregnancy is likely and where they are in their cycle

SDM users can rely on a color-coded set of beads, known as CycleBeads™ (Figure 1) to help identify fertile and non-fertile days and monitor cycle length. Each bead represents a day of the cycle, and an 'O' ring is moved each day to the next bead to track the cycle. On brown bead days, the risk of pregnancy is extremely low; on the white bead days, the risk of pregnancy is high. CycleBeads cost approximately \$1.25–\$1.50 to manufacture and get into a distribution system. Their expected product life is more than 2 years, for an annual cost of well under \$0.75.

Introducing the SDM represents a cost-effective strategy for helping couples achieve their reproductive goals. Given the urgency of the donor gap, the SDM merits consideration in different settings, such as those described below.

1. *High use of traditional methods.* In Bolivia, for example, where 48% of contraceptive prevalence is due to use of traditional methods, the SDM would help users of periodic abstinence to identify the days of the cycle when pregnancy is likely to occur.¹⁶ Similarly, users of withdrawal could also benefit from knowing the days when pregnancy is likely to occur so that on those days they might use barrier methods or avoid intercourse.

2. *High unmet need for family planning.* In Uttar Pradesh, India, unmet need for family planning is approximately 25% among married women of reproductive age.¹⁷ Underlying this unmet need is a contraceptive prevalence of 28.1%, of which more than half is due to female sterilisation. In such a setting many women hesitate to use hormonal contraception for fear that it will make them subfecund or because of prolonged breastfeeding.¹¹ The SDM could be a low-cost solution to many women's family planning needs in such settings.

3. *Chronic depletion of contraceptive commodities.* For a number of reasons, Romania has frequently experienced regular depletion of stocks of contraceptive commodities.¹⁸ In 1999, only 27% of women in union living used modern methods; reliance on withdrawal and sporadic use of condoms contribute to both high method failure and high abortion rates.^{18,19} The SDM could be introduced as both a stopgap measure when supplies are depleted and as an alternative low-cost method into the programme mix.

Further analysis will draw on recent demographic and health survey data and use computer simulations to explore the cost-effectiveness of introducing the SDM into such

settings and examine issues related to cost and fertility rates. In the context of shrinking donor support for contraceptive commodities, the SDM provides an economical, effective option that has the potential to respond to both programme and individual needs.

Conclusions

The warning to the reproductive health community is clear: mind the gap. The growing donor gap could have some significant negative consequences. However, it also offers an opportunity to reassess policies for family planning programmes, including the availability of effective, low-cost methods such as the SDM.
